Checking ASHIFT On Existing Pools

So I have an existing pool that was created several years ago on an old build of FreeNAS, and I wanted to check and see if the ashift was set correctly for 4K, meaning I want an `ashift=12` ($2^{12}=4096$). What does a quick Google tell me to do?

```
[root@server] ~# zpool get all | grep ashift
[root@server] ~#
```

Huh... nothing. That's odd.

```
[root@server] ~# zpool get all
NAME          PROPERTY      VALUE      SOURCE
Array1        size          2.72T     -
Array1        capacity      13%        -

```

Looking at just the `zpool get all` output, looks like the `ashift` attribute is missing. I'm guessing that the `ashift` attribute wasn't specified upon pool creation, leaving it up to the drive to report whether it is a 4K drive or not. Another round of Google reveals the `zdb -C` command. Let's try that.

```

[root@server] ~# zdb -C | grep ashift
      ashift: 9

```

Huh. `ashift=9` means 512... and that's no good. But wait...

```
[root@server] ~# zdb -C

```

There we go. Now let's that down.

```
[root@server] ~# zdb -U /data/zfs/zpool.cache | grep ashift  
  ashift: 12
```

And we have our answer.

[Original Article](#)

Migrating the iocage Dataset to Another Pool

First, you migrate your pools like this :

```
iocage stop ALL
zfs unmount -f tank/iocage
zfs snapshot -r tank/iocage@migration
zfs send -R tank/iocage@migration | zfs receive -v dozer/iocage
iocage clean -a
zfs destroy -f tank/iocage
iocage activate dozer
zfs destroy -r dozer/iocage@migration
```

Here, you should use your own pool names.

The old pool is named `tank`, the new one `dozer`

Then, you could need to edit your jail mount points.

To do this, you have to :

1. Set `nano` as your editor (optional if you know how to search and replace with `vi`)

```
EDITOR=/usr/local/bin/nano; export EDITOR
```

Then edit the `fstab` of your jails

```
iocage fstab -e yourjail
```

Then do search and replace all with `nano`, searching with your old mountpoint `/mnt/tank/iocage` with `/mnt/dozer/iocage`

Tested on 11.2U1

Querying ZFS Storage Pool Status

The `zpool list` command provides several ways to request information regarding pool status. The information available generally falls into three categories: basic usage information, I/O statistics, and health status. All three types of storage pool information are covered in this section.

- [Displaying Information About ZFS Storage Pools](#)
- [Viewing I/O Statistics for ZFS Storage Pools](#)
- [Determining the Health Status of ZFS Storage Pools](#)

Displaying Information About ZFS Storage Pools

You can use the `zpool list` command to display basic information about pools.

Listing Information About All Storage Pools or a Specific Pool

With no arguments, the `zpool list` command displays the following information for all pools on the system:

```
# zpool list
NAME                SIZE    ALLOC  FREE   CAP  HEALTH  ALTR00T
tank                80.0G   22.3G  47.7G  28%  ONLINE  -
dozer               1.2T    384G   816G   32%  ONLINE  -
```

This command output displays the following information:

`NAME`

The name of the pool.

`SIZE`

The total size of the pool, equal to the sum of the sizes of all top-level virtual devices.

ALLOC

The amount of physical space allocated to all datasets and internal metadata. Note that this amount differs from the amount of disk space as reported at the file system level.

For more information about determining available file system space, see [ZFS Disk Space Accounting](#).

FREE

The amount of unallocated space in the pool.

CAP (CAPACITY)

The amount of disk space used, expressed as a percentage of the total disk space.

HEALTH

The current health status of the pool.

For more information about pool health, see [Determining the Health Status of ZFS Storage Pools](#).

ALTROOT

The alternate root of the pool, if one exists.

For more information about alternate root pools, see [Using ZFS Alternate Root Pools](#).

You can also gather statistics for a specific pool by specifying the pool name. For example:

```
# zpool list tank
NAME                SIZE    ALLOC  FREE   CAP  HEALTH  ALTROOT
tank                80.0G   22.3G  47.7G  28%  ONLINE  -
```

Listing Specific Storage Pool Statistics

Specific statistics can be requested by using the `-o` option. This option provides custom reports or a quick way to list pertinent information. For example, to list only the name and size of each pool, you use the following syntax:

```
# zpool list -o name,size
NAME                SIZE
tank                80.0G
dozer               1.2T
```

The column names correspond to the properties that are listed in [Listing Information About All Storage Pools or a Specific Pool](#).

Scripting ZFS Storage Pool Output

The default output for the `zpool list` command is designed for readability and is not easy to use as part of a shell script. To aid programmatic uses of the command, the `-H` option can be used to suppress the column headings and separate fields by tabs, rather than by spaces. For example, to request a list of all pool names on the system, you would use the following syntax:

```
# zpool list -Ho name
tank
dozer
```

Here is another example:

```
# zpool list -H -o name,size
tank    80.0G
dozer   1.2T
```

Displaying ZFS Storage Pool Command History

ZFS automatically logs successful `zfs` and `zpool` commands that modify pool state information. This information can be displayed by using the `zpool history` command.

For example, the following syntax displays the command output for the root pool:

```
# zpool history
History for 'rpool':
2010-05-11.10:18:54 zpool create -f -o failmode=continue -R /a -m legacy -o
cachefile=/tmp/root/etc/zfs/zpool.cache rpool mirror c1t0d0s0 c1t1d0s0
2010-05-11.10:18:55 zfs set canmount=noauto rpool
2010-05-11.10:18:55 zfs set mountpoint=/rpool rpool
2010-05-11.10:18:56 zfs create -o mountpoint=legacy rpool/ROOT
2010-05-11.10:18:57 zfs create -b 8192 -V 2048m rpool/swap
2010-05-11.10:18:58 zfs create -b 131072 -V 1536m rpool/dump
2010-05-11.10:19:01 zfs create -o canmount=noauto rpool/ROOT/zfsBE
```

```
2010-05-11.10:19:02 zpool set bootfs=rpool/ROOT/zfsBE rpool
2010-05-11.10:19:02 zfs set mountpoint=/ rpool/ROOT/zfsBE
2010-05-11.10:19:03 zfs set canmount=on rpool
2010-05-11.10:19:04 zfs create -o mountpoint=/export rpool/export
2010-05-11.10:19:05 zfs create rpool/export/home
2010-05-11.11:11:10 zpool set bootfs=rpool rpool
2010-05-11.11:11:10 zpool set bootfs=rpool/ROOT/zfsBE rpool
```

You can use similar output on your system to identify the **actual** ZFS commands that were executed to troubleshoot an error condition.

The features of the history log are as follows:

- The log cannot be disabled.
- The log is saved persistently on disk, which means that the log is saved across system reboots.
- The log is implemented as a ring buffer. The minimum size is 128 KB. The maximum size is 32 MB.
- For smaller pools, the maximum size is capped at 1 percent of the pool size, where the size is determined at pool creation time.
- The log requires no administration, which means that tuning the size of the log or changing the location of the log is unnecessary.

To identify the command history of a specific storage pool, use syntax similar to the following:

```
# zpool history tank
History for 'tank':
2010-05-13.14:13:15 zpool create tank mirror c1t2d0 c1t3d0
2010-05-13.14:21:19 zfs create tank/snaps
2010-05-14.08:10:29 zfs create tank/ws01
2010-05-14.08:10:54 zfs snapshot tank/ws01@now
2010-05-14.08:11:05 zfs clone tank/ws01@now tank/ws01bugfix
```

Use the `-l` option to display a long format that includes the user name, the host name, and the zone in which the operation was performed. For example:

```
# zpool history -l tank
History for 'tank':
2010-05-13.14:13:15 zpool create tank mirror c1t2d0 c1t3d0 [user root on neo]
2010-05-13.14:21:19 zfs create tank/snaps [user root on neo]
2010-05-14.08:10:29 zfs create tank/ws01 [user root on neo]
2010-05-14.08:10:54 zfs snapshot tank/ws01@now [user root on neo]
2010-05-14.08:11:05 zfs clone tank/ws01@now tank/ws01bugfix [user root on neo]
```

Use the `-i` option to display internal event information that can be used for diagnostic purposes. For example:

```
# zpool history -i tank
2010-05-13.14:13:15 zpool create -f tank mirror c1t2d0 c1t23d0
2010-05-13.14:13:45 [internal pool create txg:6] pool spa 19; zfs spa 19; zpl 4;...
2010-05-13.14:21:19 zfs create tank/snaps
2010-05-13.14:22:02 [internal replay_inc_sync txg:20451] dataset = 41
2010-05-13.14:25:25 [internal snapshot txg:20480] dataset = 52
2010-05-13.14:25:25 [internal destroy_begin_sync txg:20481] dataset = 41
2010-05-13.14:25:26 [internal destroy txg:20488] dataset = 41
2010-05-13.14:25:26 [internal reservation set txg:20488] 0 dataset = 0
2010-05-14.08:10:29 zfs create tank/ws01
2010-05-14.08:10:54 [internal snapshot txg:53992] dataset = 42
2010-05-14.08:10:54 zfs snapshot tank/ws01@now
2010-05-14.08:11:04 [internal create txg:53994] dataset = 58
2010-05-14.08:11:05 zfs clone tank/ws01@now tank/ws01bugfix
```

Viewing I/O Statistics for ZFS Storage Pools

To request I/O statistics for a pool or specific virtual devices, use the `zpool iostat` command. Similar to the `iostat` command, this command can display a static snapshot of all I/O activity, as well as updated statistics for every specified interval. The following statistics are reported:

`alloc capacity`

The amount of data currently stored in the pool or device. This amount differs from the amount of disk space available to actual file systems by a small margin due to internal implementation details.

For more information about the differences between pool space and dataset space, see [ZFS Disk Space Accounting](#).

`free capacity`

The amount of disk space available in the pool or device. As with the used statistic, this amount differs from the amount of disk space available to datasets by a small margin.

`read operations`

The number of read I/O operations sent to the pool or device, including metadata requests.

`write operations`

The number of write I/O operations sent to the pool or device.

`read bandwidth`

The bandwidth of all read operations (including metadata), expressed as units per second.

`write bandwidth`

The bandwidth of all write operations, expressed as units per second.

Listing Pool-Wide I/O Statistics

With no options, the `zpool iostat` command displays the accumulated statistics since boot for all pools on the system. For example:

```
# zpool iostat
          capacity      operations      bandwidth
pool      alloc  free   read  write  read  write
-----
rpool     6.05G  61.9G     0     0    786   107
tank      31.3G  36.7G     4     1  296K  86.1K
-----
```

Because these statistics are cumulative since boot, bandwidth might appear low if the pool is relatively idle. You can request a more accurate view of current bandwidth usage by specifying an interval. For example:

```
# zpool iostat tank 2
          capacity      operations      bandwidth
pool      alloc  free   read  write  read  write
-----
tank      18.5G  49.5G     0    187     0  23.3M
tank      18.5G  49.5G     0    464     0  57.7M
tank      18.5G  49.5G     0    457     0  56.6M
tank      18.8G  49.2G     0    435     0  51.3M
```

In this example, the command displays usage statistics for the pool tank every two seconds until you type Control-C. Alternately, you can specify an additional `count` argument, which causes the command to terminate after the specified number of iterations. For example, `zpool iostat 2 3` would print a summary every two seconds for three iterations, for a total of six seconds. If there is only a single pool, then the statistics are displayed on consecutive lines. If more than one pool exists, then an additional dashed line delineates each iteration to provide visual separation.

Listing Virtual Device I/O Statistics

In addition to pool-wide I/O statistics, the `zpool iostat` command can display I/O statistics for virtual devices. This command can be used to identify abnormally slow devices or to observe the distribution of I/O generated by ZFS. To request the complete virtual device layout as well as all I/O statistics, use the `zpool iostat -v` command. For example:

```
# zpool iostat -v
          capacity      operations      bandwidth
pool      alloc  free   read  write  read  write
-----  -
rpool     6.05G  61.9G    0     0    785   107
  mirror  6.05G  61.9G    0     0    785   107
    c1t0d0s0  -     -     0     0    578   109
    c1t1d0s0  -     -     0     0    595   109
-----  -
tank      36.5G  31.5G    4     1   295K  146K
  mirror  36.5G  31.5G   126   45  8.13M  4.01M
    c1t2d0  -     -     0     3   100K  386K
    c1t3d0  -     -     0     3   104K  386K
-----  -
```

Note two important points when viewing I/O statistics for virtual devices:

- First, disk space usage statistics are only available for top-level virtual devices. The way in which disk space is allocated among mirror and RAID-Z virtual devices is particular to the implementation and not easily expressed as a single number.
- Second, the numbers might not add up exactly as you would expect them to. In particular, operations across RAID-Z and mirrored devices will not be exactly equal. This difference is particularly noticeable immediately after a pool is created, as a significant amount of I/O is done directly to the disks as part of pool creation, which is not accounted for at the mirror level. Over time, these numbers gradually equalize. However, broken, unresponsive, or offline devices can affect this symmetry as well.

You can use the same set of options (interval and count) when examining virtual device statistics.

Determining the Health Status of ZFS Storage Pools

ZFS provides an integrated method of examining pool and device health. The health of a pool is determined from the state of all its devices. This state information is displayed by using the `zpool status` command. In addition, potential pool and device failures are reported by `fmfd`, displayed on the system console, and logged in the `/var/adm/messages` file.

This section describes how to determine pool and device health. This chapter does not document how to repair or recover from unhealthy pools. For more information about troubleshooting and data recovery, see [Chapter 11, Oracle Solaris ZFS Troubleshooting and Pool Recovery](#).

Each device can fall into one of the following states:

ONLINE

The device or virtual device is in normal working order. Although some transient errors might still occur, the device is otherwise in working order.

DEGRADED

The virtual device has experienced a failure but can still function. This state is most common when a mirror or RAID-Z device has lost one or more constituent devices. The fault tolerance of the pool might be compromised, as a subsequent fault in another device might be unrecoverable.

FAULTED

The device or virtual device is completely inaccessible. This status typically indicates total failure of the device, such that ZFS is incapable of sending data to it or receiving data from it. If a top-level virtual device is in this state, then the pool is completely inaccessible.

OFFLINE

The device has been explicitly taken offline by the administrator.

UNAVAIL

The device or virtual device cannot be opened. In some cases, pools with `UNAVAIL` devices appear in `DEGRADED` mode. If a top-level virtual device is `UNAVAIL`, then nothing in the pool can be accessed.

REMOVED

The device was physically removed while the system was running. Device removal detection is hardware-dependent and might not be supported on all platforms.

The health of a pool is determined from the health of all its top-level virtual devices. If all virtual devices are `ONLINE`, then the pool is also `ONLINE`. If any one of the virtual devices is `DEGRADED` or `UNAVAIL`, then the pool is also `DEGRADED`. If a top-level virtual device is `FAULTED` or `OFFLINE`, then the pool is also `FAULTED`. A pool in the `FAULTED` state is completely inaccessible. No data can be recovered until the necessary devices are attached or repaired. A pool in the `DEGRADED` state continues to run, but you might not achieve the same level of data redundancy or data throughput than if the pool were online.

Basic Storage Pool Health Status

You can quickly review pool health status by using the `zpool status` command as follows:

```
# zpool status -x
all pools are healthy
```

Specific pools can be examined by specifying a pool name in the command syntax. Any pool that is not in the `ONLINE` state should be investigated for potential problems, as described in the next section.

Detailed Health Status

You can request a more detailed health summary status by using the `-v` option. For example:

```
# zpool status -v tank
pool: tank
state: DEGRADED
status: One or more devices could not be opened. Sufficient replicas exist for
the pool to continue functioning in a degraded state.
action: Attach the missing device and online it using 'zpool online'.
see: http://www.sun.com/msg/ZFS-8000-2Q
scrub: scrub completed after 0h0m with 0 errors on Wed Jan 20 15:13:59 2010
config:

    NAME      STATE      READ WRITE CKSUM
    tank      DEGRADED   0     0     0
      mirror-0 DEGRADED   0     0     0
        clt0d0 ONLINE     0     0     0
        clt1d0 UNAVAIL    0     0     0  cannot open

errors: No known data errors
```

This output displays a complete description of why the pool is in its current state, including a readable description of the problem and a link to a knowledge article for more information. Each knowledge article provides up-to-date information about the best way to recover from your current problem. Using the detailed configuration information, you can determine which device is damaged and how to repair the pool.

In the preceding example, the faulted device should be replaced. After the device is replaced, use the `zpool online` command to bring the device online. For example:

```
# zpool online tank c1t0d0
Bringing device c1t0d0 online
# zpool status -x
all pools are healthy
```

If the `autoreplace` property is on, you might not have to online the replaced device.

If a pool has an offline device, the command output identifies the problem pool. For example:

```
# zpool status -x
pool: tank
state: DEGRADED
status: One or more devices has been taken offline by the administrator.
       Sufficient replicas exist for the pool to continue functioning in a
       degraded state.
action: Online the device using 'zpool online' or replace the device with
       'zpool replace'.
scrub: resilver completed after 0h0m with 0 errors on Wed Jan 20 15:15:09 2010
config:

      NAME      STATE      READ WRITE CKSUM
      tank      DEGRADED   0     0     0
          mirror-0  DEGRADED   0     0     0
              c1t0d0  ONLINE     0     0     0
              c1t1d0  OFFLINE    0     0     0 48K resilvered

errors: No known data errors
```

The `READ` and `WRITE` columns provide a count of I/O errors that occurred on the device, while the `CKSUM` column provides a count of uncorrectable checksum errors that occurred on the device. Both error counts indicate a potential device failure, and some corrective action is needed. If non-zero errors are reported for a top-level virtual device, portions of your data might have become inaccessible.

The `errors:` field identifies any known data errors.

In the preceding example output, the offline device is not causing data errors.

For more information about diagnosing and repairing faulted pools and data, see [Chapter 11, Oracle Solaris ZFS Troubleshooting and Pool Recovery](#).

Repairing Damaged Data

The following sections describe how to identify the type of data corruption and how to repair the data, if possible.

- [Identifying the Type of Data Corruption](#)
- [Repairing a Corrupted File or Directory](#)
- [Repairing ZFS Storage Pool-Wide Damage](#)

ZFS uses checksums, redundancy, and self-healing data to minimize the risk of data corruption. Nonetheless, data corruption can occur if a pool isn't redundant, if corruption occurred while a pool was degraded, or an unlikely series of events conspired to corrupt multiple copies of a piece of data. Regardless of the source, the result is the same: The data is corrupted and therefore no longer accessible. The action taken depends on the type of data being corrupted and its relative value. Two basic types of data can be corrupted:

- Pool metadata - ZFS requires a certain amount of data to be parsed to open a pool and access datasets. If this data is corrupted, the entire pool or portions of the dataset hierarchy will become unavailable.
- Object data - In this case, the corruption is within a specific file or directory. This problem might result in a portion of the file or directory being inaccessible, or this problem might cause the object to be broken altogether.

Data is verified during normal operations as well as through a scrubbing. For information about how to verify the integrity of pool data, see [Checking ZFS File System Integrity](#).

Identifying the Type of Data Corruption

By default, the `zpool status` command shows only that corruption has occurred, but not where this corruption occurred. For example:

```
# zpool status monkey
  pool: monkey
  state: ONLINE
status: One or more devices has experienced an error resulting in data
       corruption. Applications may be affected.
action: Restore the file in question if possible.  Otherwise restore the
       entire pool from backup.
see: http://www.sun.com/msg/ZFS-8000-8A
```

```
scrub: scrub completed after 0h0m with 8 errors on Tue Jul 13 13:17:32 2010
```

```
config:
```

NAME	STATE	READ	WRITE	CKSUM
monkey	ONLINE	8	0	0
c1t1d0	ONLINE	2	0	0
c2t5d0	ONLINE	6	0	0

```
errors: 8 data errors, use '-v' for a list
```

Each error indicates only that an error occurred at a given point in time. Each error is not necessarily still present on the system. Under normal circumstances, this is the case. Certain temporary outages might result in data corruption that is automatically repaired after the outage ends. A complete scrub of the pool is guaranteed to examine every active block in the pool, so the error log is reset whenever a scrub finishes. If you determine that the errors are no longer present, and you don't want to wait for a scrub to complete, reset all errors in the pool by using the `zpool online` command.

If the data corruption is in pool-wide metadata, the output is slightly different. For example:

```
# zpool status -v morpheus
pool: morpheus
  id: 1422736890544688191
  state: FAULTED
status: The pool metadata is corrupted.
action: The pool cannot be imported due to damaged devices or data.
  see: http://www.sun.com/msg/ZFS-8000-72
config:

  morpheus    FAULTED    corrupted data
    c1t10d0    ONLINE
```

In the case of pool-wide corruption, the pool is placed into the `FAULTED` state because the pool cannot provide the required redundancy level.

Repairing a Corrupted File or Directory

If a file or directory is corrupted, the system might still function, depending on the type of corruption. Any damage is effectively unrecoverable if no good copies of the data exist on the system. If the data is valuable, you must restore the affected data from backup. Even so, you might be able to recover from this corruption without restoring the entire pool.

If the damage is within a file data block, then the file can be safely removed, thereby clearing the error from the system. Use the `zpool status -v` command to display a list of file names with persistent errors. For example:

```
# zpool status -v
pool: monkey
state: ONLINE
status: One or more devices has experienced an error resulting in data
corruption. Applications may be affected.
action: Restore the file in question if possible. Otherwise restore the
entire pool from backup.
see: http://www.sun.com/msg/ZFS-8000-8A
scrub: scrub completed after 0h0m with 8 errors on Tue Jul 13 13:17:32 2010
config:

    NAME      STATE    READ WRITE CKSUM
    monkey    ONLINE   8     0     0
    c1t1d0    ONLINE   2     0     0
    c2t5d0    ONLINE   6     0     0

errors: Permanent errors have been detected in the following files:

/monkey/a.txt
/monkey/bananas/b.txt
/monkey/sub/dir/d.txt
monkey/ghost/e.txt
/monkey/ghost/boo/f.txt
```

The list of file names with persistent errors might be described as follows:

- If the full path to the file is found and the dataset is mounted, the full path to the file is displayed. For example:

```
/monkey/a.txt
```

- If the full path to the file is found, but the dataset is not mounted, then the dataset name with no preceding slash (/), followed by the path within the dataset to the file, is displayed. For example:

```
monkey/ghost/e.txt
```

- If the object number to a file path cannot be successfully translated, either due to an error or because the object doesn't have a real file path associated with it, as is the case for a `dnode_t`, then the dataset name followed by the object's number is displayed. For example:

```
monkey/dnode: <0x0>
```

- If an object in the metaobject set (MOS) is corrupted, then a special tag of `<metadata>`, followed by the object number, is displayed.

If the corruption is within a directory or a file's metadata, the only choice is to move the file elsewhere. You can safely move any file or directory to a less convenient location, allowing the original object to be restored in its place.

Repairing ZFS Storage Pool-Wide Damage

If the damage is in pool metadata and that damage prevents the pool from being opened or imported, then the following options are available:

- Attempt to recover the pool by using the `zpool clear -F` command or the `zpool import -F` command. These commands attempt to roll back the last few pool transactions to an operational state. You can use the `zpool status` command to review a damaged pool and the recommended recovery steps. For example:

```
# zpool status
pool: tpool
state: FAULTED
status: The pool metadata is corrupted and the pool cannot be opened.
action: Recovery is possible, but will result in some data loss.
        Returning the pool to its state as of Wed Jul 14 11:44:10 2010
        should correct the problem. Approximately 5 seconds of data
        must be discarded, irreversibly. Recovery can be attempted
        by executing 'zpool clear -F tpool'. A scrub of the pool
        is strongly recommended after recovery.
see: http://www.sun.com/msg/ZFS-8000-72
scrub: none requested
config:
```

NAME	STATE	READ	WRITE	CKSUM
------	-------	------	-------	-------

```
tpool      FAULTED      0      0      1  corrupted data
c1t1d0    ONLINE       0      0      2
c1t3d0    ONLINE       0      0      4
```

The recovery process as described above is to use the following command:

```
# zpool clear -F tpool
```

If you attempt to import a damaged storage pool, you will see messages similar to the following:

```
# zpool import tpool
cannot import 'tpool': I/O error
    Recovery is possible, but will result in some data loss.
    Returning the pool to its state as of Wed Jul 14 11:44:10 2010
    should correct the problem.  Approximately 5 seconds of data
    must be discarded, irreversibly.  Recovery can be attempted
    by executing 'zpool import -F tpool'.  A scrub of the pool
    is strongly recommended after recovery.
```

The recovery process as described above is to use the following command:

```
# zpool import -F tpool
Pool tpool returned to its state as of Wed Jul 14 11:44:10 2010.
Discarded approximately 5 seconds of transactions
```

If the damaged pool is in the `zpool.cache` file, the problem is discovered when the system is booted, and the damaged pool is reported in the `zpool status` command. If the pool isn't in the `zpool.cache` file, it won't successfully import or open and you'll see the damaged pool messages when you attempt to import the pool.

If the pool cannot be recovered by the pool recovery method described above, you must restore the pool and all its data from a backup copy. The mechanism you use varies widely depending on the pool configuration and backup strategy. First, save the configuration as displayed by the `zpool status` command so that you can recreate it after the pool is destroyed. Then, use the `zpool destroy -f` command to destroy the pool. Also, keep a file describing the layout of the datasets and the various locally set properties somewhere safe, as this information will become inaccessible if the pool is ever rendered inaccessible. With the pool configuration and dataset layout, you can reconstruct your complete configuration after destroying the pool. The data can then be populated by using whatever backup or restoration strategy you use.

Repairing a Corrupted File or Directory

If a file or directory is corrupted, the system might still function, depending on the type of corruption. Any damage is effectively unrecoverable if no good copies of the data exist on the system. If the data is valuable, you must restore the affected data from backup. Even so, you might be able to recover from this corruption without restoring the entire pool.

If the damage is within a file data block, then the file can be safely removed, thereby clearing the error from the system. Use the `zpool status -v` command to display a list of file names with persistent errors. For example:

```
# zpool status tank -v
pool: tank
state: ONLINE
status: One or more devices has experienced an error resulting in data
corruption. Applications may be affected.
action: Restore the file in question if possible. Otherwise restore the
entire pool from backup.
see: http://support.oracle.com/msg/ZFS-8000-8A
config:

NAME                                STATE      READ WRITE CKSUM
tank                                ONLINE    4     0     0
c0t5000C500335E106Bd0              ONLINE    0     0     0
c0t5000C500335FC3E7d0              ONLINE    4     0     0

errors: Permanent errors have been detected in the following files:
/tank/file.1
/tank/file.2
```

The list of file names with persistent errors might be described as follows:

- If the full path to the file is found and the dataset is mounted, the full path to the file is displayed. For example:

```
/monkey/a.txt
```

- If the full path to the file is found, but the dataset is not mounted, then the dataset name with no preceding slash (/), followed by the path within the dataset to the file, is displayed. For example:

```
monkey/ghost/e.txt
```

- If the object number to a file path cannot be successfully translated, either due to an error or because the object doesn't have a real file path associated with it, as is the case for a `dnode_t`, then the dataset name followed by the object's number is displayed. For example:

```
monkey/dnode:<0x0>
```

- If an object in the metaobject set (MOS) is corrupted, then a special tag of `<metadata>`, followed by the object number, is displayed.

You can attempt to resolve more minor data corruption by using scrubbing the pool and clearing the pool errors in multiple iterations. If the first scrub and clear iteration does not resolve the corrupted files, run them again. For example:

```
# zpool scrub tank
# zpool clear tank
```

If the corruption is within a directory or a file's metadata, the only choice is to move the file elsewhere. You can safely move any file or directory to a less convenient location, allowing the original object to be restored in its place.

Repairing Corrupted Data With Multiple Block References

If a damaged file system has corrupted data with multiple block references, such as snapshots, the `zpool status -v` command cannot display all corrupted data paths. The current `zpool status` reporting of corrupted data is limited by the amount of metadata corruption and if any blocks have been reused after the `zpool status` command is executed. Deduplicated blocks makes reporting all corrupted data even more complicated.

If you have corrupted data and the `zpool status -v` command identifies that snapshot data is impacted, then considering running the following command to identify additional corrupted paths:

[Original Article](#)

Using smartctl to get SMART status information on your hard drives

Computer hard drives today come with SMART (Self-Monitoring, Analysis, and Reporting Technology) built-in, which allows you to see the status or overall “health” of a hard drive. This information is invaluable in providing early warning signs of problems with a hard drive.

All Linux distributions provide the smartmontools package, which contain the smartctl program used to display SMART information from attached drives. This package also provides the smartd daemon which periodically polls the drives to obtain SMART information.

Using smartd is essential as it can let you know immediately when a SMART attribute fails. To begin, edit `/etc/smartd.conf` and add entries for your drives:

```
/dev/sda -d ata -H -m root
/dev/sdb -d ata -H -m root
```

The above tells smartd to perform a very silent check and to email the root user if the overall SMART health status fails. It also tells smartd that these are ATA devices. There are a number of other options that can be added as well; the `smartd.conf` file has examples of these.

When smartd is configured, make sure to enable the monitoring daemon if it is not already started. On a Red Hat Enterprise Linux system, use:

```
# chkconfig smartd on
# service smartd start
```

The smartctl program also allows for you to view and test SMART attributes of a drive. You can quickly check the overall health of a drive by using:

```
# smartctl -H /dev/sda
smartctl version 5.38 [x86_64-redhat-linux-gnu] Copyright (C) 2002-8 Bruce Allen
Home page is http://smartmontools.sourceforge.net/
=== START OF READ SMART DATA SECTION ===
SMART overall-health self-assessment test result: PASSED
```

Obtaining information on the drive is useful as well. With the `-i` option, you can view the type of drive, its serial number, and so forth. In a system with a lot of drives, having this information recorded can assist in knowing which drive device (i.e., `/dev/sda`) corresponds with which physical drive. For instance:

```
# smartctl -i /dev/sda
smartctl version 5.38 [x86_64-redhat-linux-gnu] Copyright (C) 2002-8 Bruce Allen
Home page is http://smartmontools.sourceforge.net/
=== START OF INFORMATION SECTION ===
Model Family:      Seagate Barracuda 7200.10 family
Device Model:      ST3320620AS
Serial Number:     9QF26NGD
Firmware Version:  3.AAJ
User Capacity:     320,072,933,376 bytes
Device is:         In smartctl database [for details use: -P show]
ATA Version is:    7
ATA Standard is:   Exact ATA specification draft version not indicated
Local Time is:     Sun Mar  7 14:20:18 2010 MST
SMART support is:  Available - device has SMART capability.
SMART support is:  Enabled
```

Next, the `-a` option shows the specifics of the SMART attributes and test history. This shows various SMART status information, such as the drive temperature, how many hours it has been powered on, and so forth. It also indicates when tests have been performed and what the results of those tests were.

Finally, `smartctl` can be used to initiate long and short tests for the drive. These should be run periodically to do quick, or full, self-tests of the drive:

```
# smartctl --test=short /dev/sda
# smartctl --test=long /dev/sda
# smartctl -a /dev/sda
```

The above will first perform a short test of the `/dev/sda` device. This usually takes about a minute to perform, and the `smartctl` output will tell you when you can check the results. Next, the long test: this one can take quite a bit longer (about two hours here on a 320GB SATA drive). Finally, use the `-a` option to view the results, which may look like this:

```
SMART Self-test log structure revision number 1
Num Test_Description      Status                    Remaining  LifeTime(hours)  LBA_of_first_error
# 1 Short offline         Completed without error   00%        17877             -
```

# 2	Extended offline	Completed without error	00%	8449	-
# 3	Short offline	Completed without error	00%	8446	-
# 4	Short offline	Completed without error	00%	1307	-
# 5	Short offline	Completed without error	00%	2	-
# 6	Extended offline	Self-test routine in progress	90%	17877	-

In the above example, tests have been run over the lifetime of the drive and the short offline test was recently completed without error, while there is still 90% of the extended test remaining.

Being pro-active with the health of your hard drives can pay off huge by being aware of most problems before they can lead to catastrophic failures. While SMART monitoring is not an exact thing (it won't always report failures before they occur), the chances of catching a problem and being able to retrieve data before replacing a drive are more likely to not result in data loss or other problems than if you did not use it.
